

*My interest in droughts dates back to the late 1990s – to Mathew Barlow’s doctoral research. The related papers were among the first to observationally document the influence of Pacific decadal SST variability on North American hydroclimate, making the case for a significant SST role in generation of North American droughts. Subsequent work with colleague, Alfredo Ruiz-Barradas, showed that atmospheric and terrestrial water cycles over the Great Plains were often misrepresented in the leading atmospheric-land surface general circulation models on account of a greater role for evapotranspiration (and heightened land-atmosphere interactions) in the models, limiting the models’ utility in analysis of drought mechanisms. More recent work with Bin Guan shows the striking role of the Atlantic basin, especially Atlantic Multidecadal Oscillation, in generation of North American droughts, particularly during spring and fall. The analysis with Guan leads to remarkable reconstruction of most (but not all) droughts, enabling evaluation of the basin roles and influence mechanisms.*

*My group’s observationally-rooted efforts indicate a prominent role for large-scale circulation (and related moisture transports) in regional hydroclimate variability, including North American droughts. Model-based analyses have, interestingly, advocated a greater role for local land-atmosphere interaction (and related evapotranspiration), perhaps, on account of overrepresentation of land-atmosphere interactions.*
