

Review of Lectures 9 to 17

AOSC 433/633 & CHEM 433/633

Ross Salawitch

Class Web Site: <http://www.atmos.umd.edu/~rjs/class/spr2013>

Notes:

- Review of Problem Set #4 will be held tomorrow 6:00 pm
- Last day to withdraw is 10 April
apologies for scheduling exam one day after this important deadline
- ELMS gradebook current: please let us know of any inconsistencies

9 April 2013

1

Importance of Radicals (Lectures 9 & 10)

- With a few exceptions, the only reactions between molecules that proceed at appreciable rates are those involving at least one radical
- Radicals require significant energy to form: a bond must be broken
- Radical formation is tied to absorption of photons that “photodissociate” a compound, leading to radical formation

Initiation

Propagation

Termination

This material may not be reproduced or redistributed, in whole or in part, without written permission from Ross Salawitch or Tim Canty.

2

Atmospheric Radiation

- Solar irradiance (downwelling) at top of atmosphere occurs at wavelengths between ~200 and 2000 nm (~5750 K “black body” temperature)

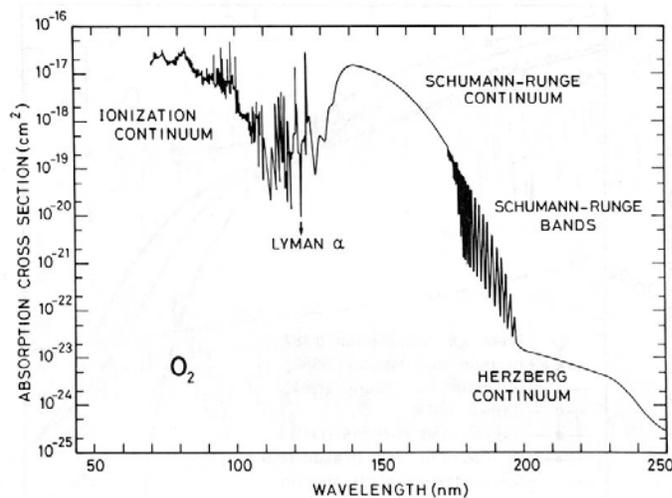

- Absorption and photodissociation in the UV occurs due to changes in the electronic state (orbital configuration) of molecules

This material may not be reproduced or redistributed, in whole or in part, without written permission from Ross Salawitch or Tim Canty.

3

Absorption Cross Section of O_2

From Brasseur & Solomon, *Aeronomy of the Middle Atmosphere*, 1986

- O_2 can not dissociate longward of ~250 nm
- All absorption shown above is dissociative (e.g., leads to production of two O atoms)
- Structure in the O_2 cross section is related to whether the initial transition involves an unbound electronic state (smooth) or involves a specific vibrational level of an electronic state (banded, due to requirement of specific quanta of energy)

This material may not be reproduced or redistributed, in whole or in part, without written permission from Ross Salawitch or Tim Canty.

4

Optical Depth of O₂ Absorption

Recall the *Beer-Lambert Law*:

$$F(z, \lambda) = F_{\text{TOA}}(\lambda) e^{-\tau(z, \lambda)} \quad (\text{TOA : Top of Atmosphere})$$

where:

$$\tau(z, \lambda) = m \int_z^{\infty} \sigma_{\lambda} [C] dz' \quad (\tau: \text{optical depth})$$

Also:

$$\int_0^{\infty} [\text{O}_2] dz' \approx 4 \times 10^{24} \text{ molecules/cm}^2$$

O ₂ Optical Depth for $\theta = 0^\circ$, $z = 0$ km			
	σ_{max} (cm ²)	τ (0 km)	$e^{-\tau}$ (0 km)
Schumann-Runge Continuum	10 ⁻¹⁷	4 × 10 ⁷	0.
Schumann-Runge Bands	10 ⁻²⁰	4 × 10 ⁴	0.
	3 × 10 ⁻²³	120	7.6 × 10 ⁻⁵³
Herzberg Continuum	10 ⁻²³	40	4.2 × 10 ⁻¹⁸

5

Optical Depth of O₃ Absorption

A typical mid-latitude column abundance for O₃ is 300 Dobson units (DU):

$$1 \text{ DU} = 2.687 \times 10^{16} \text{ molecules/cm}^2; \quad 300 \text{ DU} = 8 \times 10^{18} \text{ molecules/cm}^2$$

Aside:

$$\frac{\text{Column O}_3}{\text{Column Air}} = \frac{8 \times 10^{18}}{2 \times 10^{25}} = 0.4 \text{ parts per million} \Rightarrow \text{Ozone is a trace species!}$$

O ₃ Optical Depth for $\theta = 0^\circ$, $z = 0$ km				
	σ_{max} (cm ²)	τ (0 km)	$e^{-\tau}$ (0 km)	O ₃ Column, $\tau = 1.0$
Hartley (~220 to 280 nm)	10 ⁻¹⁷	80	1.8 × 10 ⁻³⁵	3.7 DU
Huggins (~310 to 330 nm)	10 ⁻¹⁹	0.8	0.45	372 DU
Chappuis (~500 to 700 nm)	3 × 10 ⁻²¹	0.024	~1.0	12,400 DU

8

Photolysis Frequency

For a specific spectral interval, the photolysis frequency (*partial J value*) of a gas is given by the product of its absorption cross section and the solar irradiance:

$$J_{\text{gas}}(z, \lambda) = \text{Quantum_Yield}(\lambda) \sigma_{\text{gas}}(\lambda, T) F(z, \lambda)$$

Units: $\text{s}^{-1} \text{nm}^{-1}$

The total *photolysis frequency* (*J value*) is found by integrating $J_{\text{gas}}(z, \lambda)$ over all wavelengths for which the gas photodissociates:

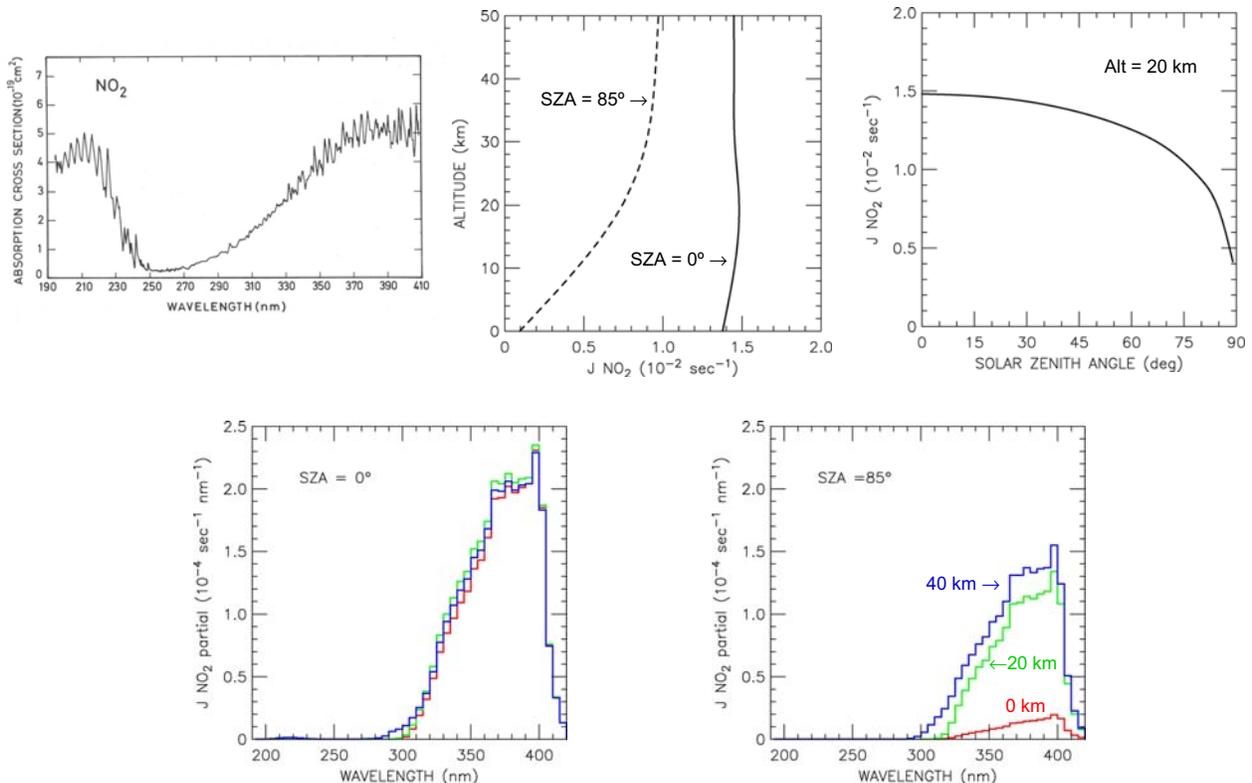

$$J_{\text{gas}}(z) = \int_{\lambda_{\text{min}}}^{\lambda_{\text{max}}} J_{\text{gas}}(z, \lambda) d\lambda$$

Units: s^{-1}

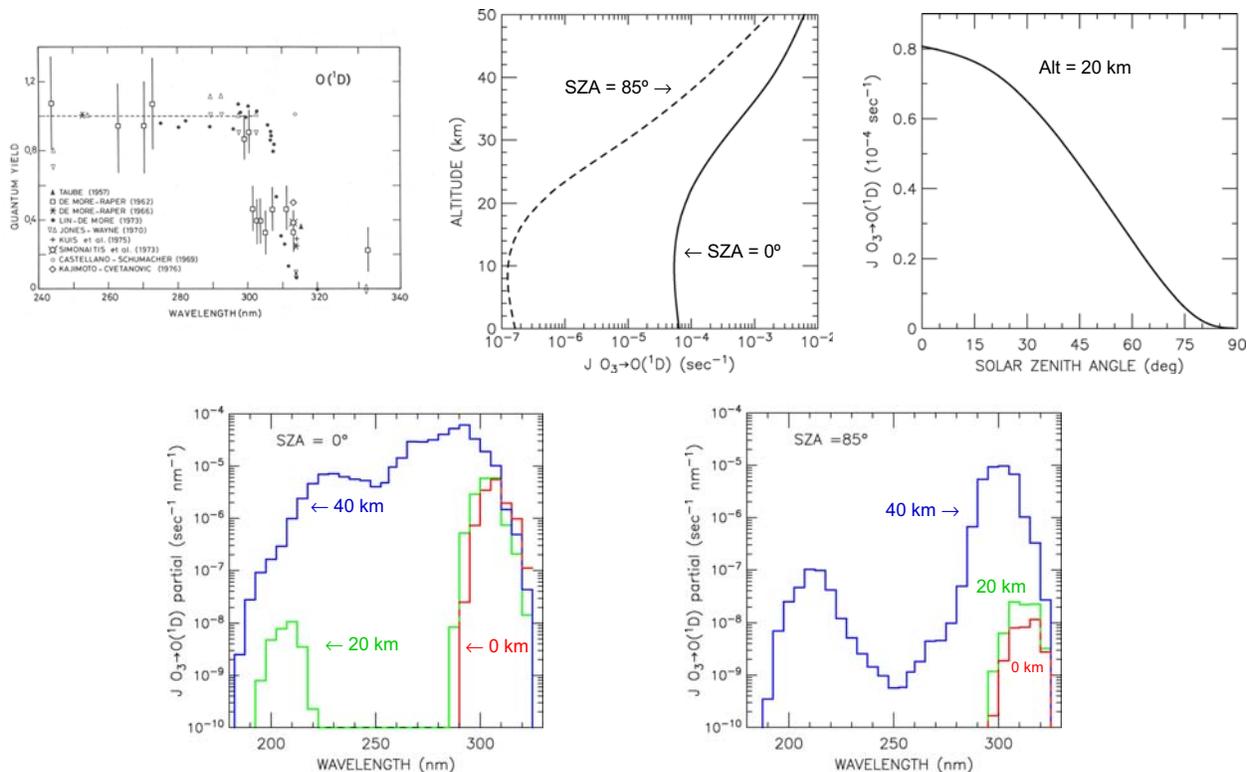

Rate of Reaction = $\frac{d\text{O}_3}{dt} = J [\text{O}_3]$; Units of J are s^{-1}

More precisely, calculations of photolysis frequencies consider the “spectral actinic flux”, which represents the amount of available photons integrated over all angles, rather than “solar irradiance”. These two quantities differ because of scattering of solar radiation by gases and aerosols, and reflection of radiation by clouds and the surface.

NO₂ Photolysis

12

Tropospheric Ozone Production versus NO

As NO_x rises:

$[\text{HO}_2]$ falls faster than $[\text{NO}]$ rises,
 leading to a decrease in the value of the product of $k [\text{NO}] [\text{HO}_2]$,
 and hence the production rate of O_3 .

Tropospheric Ozone Production versus NO_x and VOCs

Ridge: local maximum for O_3 that separates the NO_x -limited regime from and VOC limited regime

An important discovery in the past decade is that the focus on hydrocarbon emission controls to combat O_3 pollution may have been partly misdirected. Measurements and model calculations now show that O_3 production over most of the United States is primarily NO_x limited, not hydrocarbon limited. The early models were in error in part because they underestimated emissions of hydrocarbons from automobiles, and in part because they did not account for natural emission of biogenic hydrocarbons from trees and crops.

Stratospheric Ozone: Chapman Chemistry

- Production of O_3 initiated when O_2 is photodissociated by UV sunlight
- O_3 formed when resulting O atom reacts with O_2 :

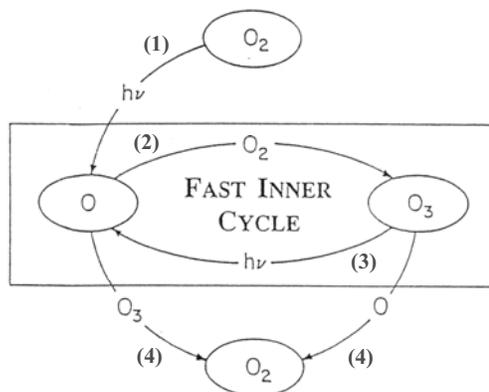

- O_3 removed by photodissociation (UV sunlight) or by reaction with O :

This reaction sequence was first worked out in the 1930s by Sidney Chapman, an English mathematician and geophysicist

Chapman Chemistry

- The cycling between O and O_2 (rxns 2 and 3) occurs *much* more rapidly than leakage into (rxn 1) or out of the system (rxn 4)
- The sum $O + O_3$ is commonly called “*odd oxygen*”

Rxn (1) produces two *odd oxygen* molecules

Rxn (4) consumes two *odd oxygen* molecules

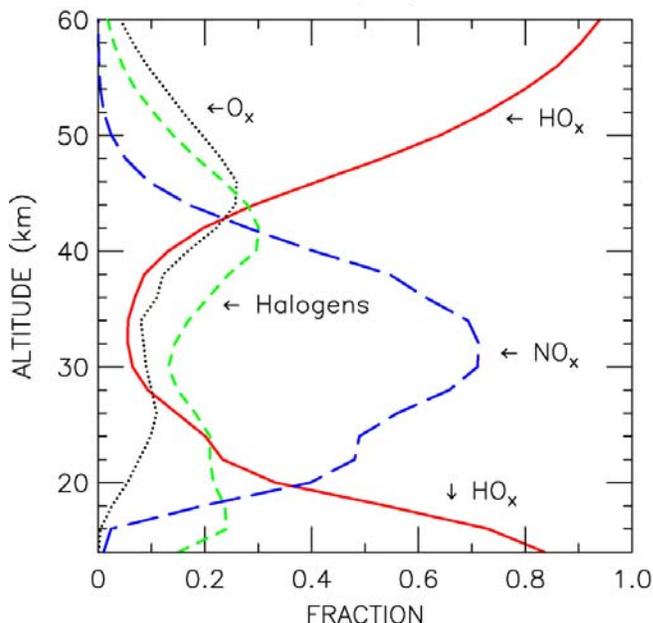

and reactions 2 and 3 recycle *odd oxygen* molecules

Stratospheric Photochemistry: Odd Oxygen Loss By Families

Fraction of O_x Loss Due to Each Catalytic Family

JPL 2002 Kinetics

35°N, Sept

Calculated fraction of odd oxygen loss due to various families of radicals

20

Tropospheric Chlorine Loading

Total Organic Chlorine (CCl_y):

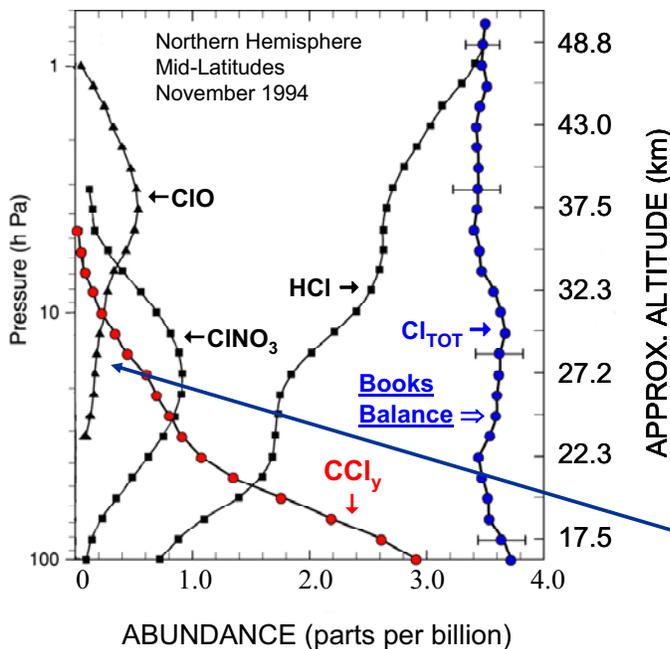

- Peaked at ~3.6 ppb around 1993
- Slowly declining
- Montreal Protocol and Amendments have banned production of CFCs

CFCs:

- long lived (50 to 100 yr lifetime)
- decompose in the stratosphere
- lose memory of emission location when enter stratosphere

Chlorine Abundance, Mid-Latitude Stratosphere

Chlorine Source Gases

Primary Sources of Chlorine for the Stratosphere in 1999

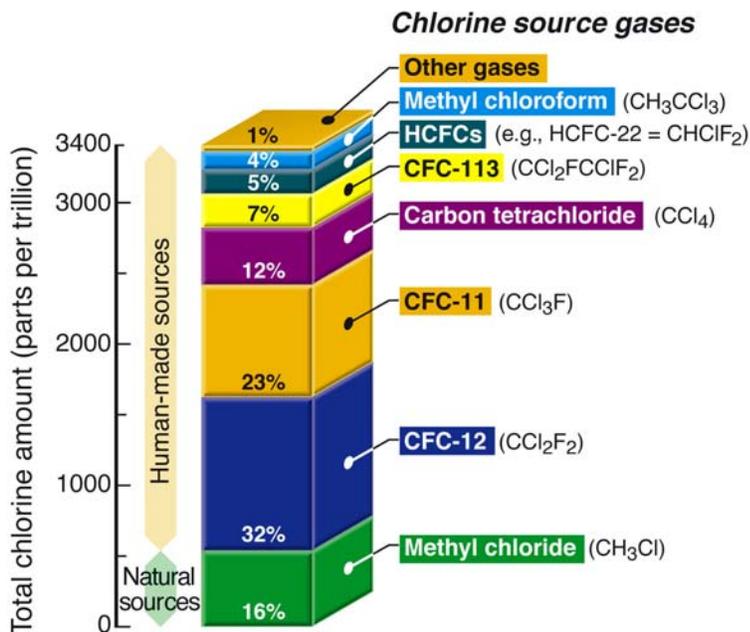

Table Q7-1. Atmospheric Lifetimes and Ozone Depletion Potentials of some halogen source gas & HFC substitute gases.

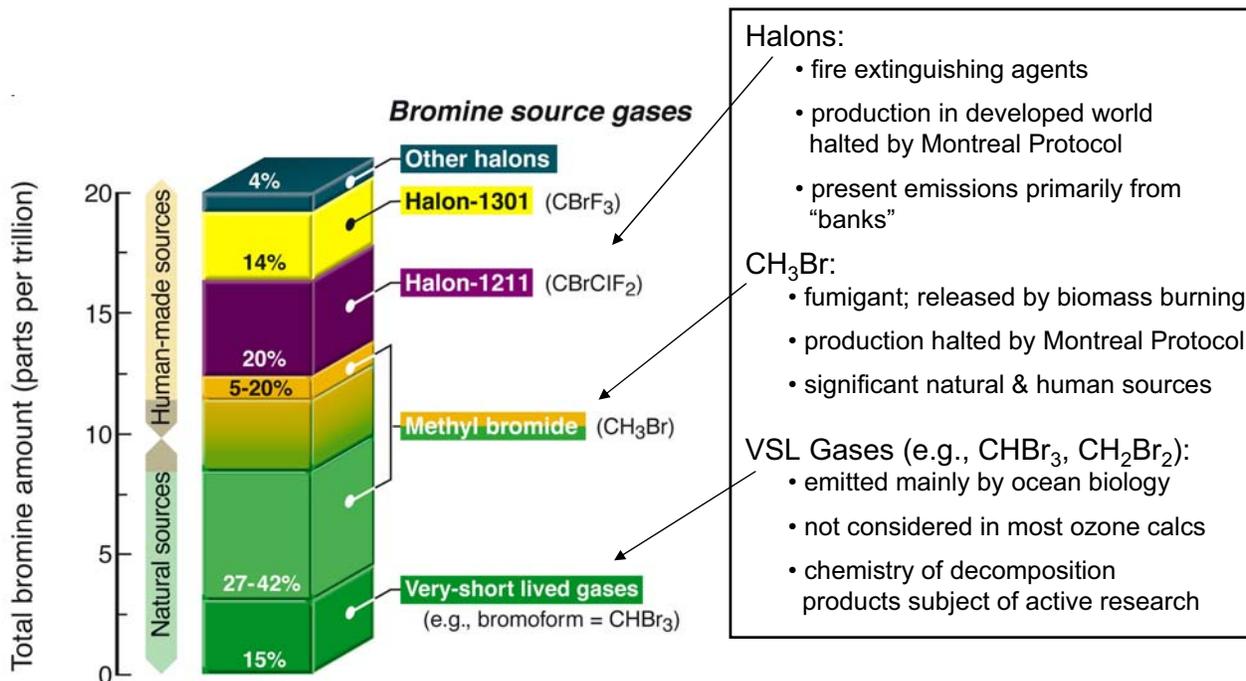

Gas	Atmospheric Lifetime (years)	Ozone Depletion Potential (ODP) ^c
Halogen source gases		
<i>Chlorine gases</i>		
CFC-11	45	1
CFC-12	100	0.82
CFC-113	85	0.85
Carbon tetrachloride (CCl_4)	26	0.82
HCFCs	1-17	0.01-0.12
Methyl chloroform (CH_3CCl_3)	5	0.16
Methyl chloride (CH_3Cl)	1	0.02
<i>Bromine gases</i>		
Halon-1301	65	15.9
Halon-1211	16	7.9
Methyl bromide (CH_3Br)	0.8	0.66
Very short-lived gases (e.g., CHBr_3)	Less than 0.5	^b very low
Hydrofluorocarbons (HFCs)		
HFC-134a	13.4	0
HFC-23	222	0

31

Future Mid-Latitude Ozone: N₂O

Ozone depleting NO_x cycles speed up with increasing N₂O throughout the middle stratosphere, where these cycles make the largest relative contribution to odd oxygen loss.

As NO₂ increases due to rising N₂O, the abundance of HO₂ and ClO radicals declines, particularly in the lower stratosphere, leading to reduced rates in the total speed of all ozone depleting cycles (red region, Fig 5a).

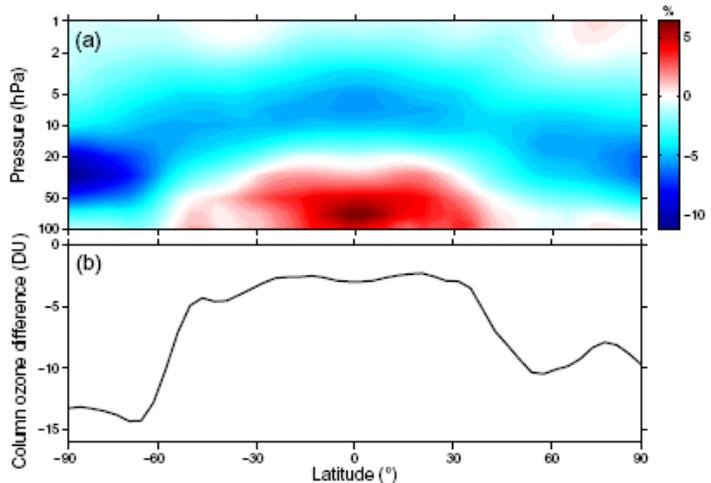

Fig. 5. (a) N₂O-8.5 ozone minus N₂O-2.6 ozone in the 2090s decade, calculated as a percentage of ozone in the N₂O-2.6 simulation. (b) 2090s-decade N₂O-8.5 total column ozone minus N₂O-2.6 total column ozone.

32

Future Mid-Latitude Ozone: CH₄

Rising CH₄ leads to ozone loss in the upper and lower stratosphere by increasing the speed of HO_x mediated loss cycles.

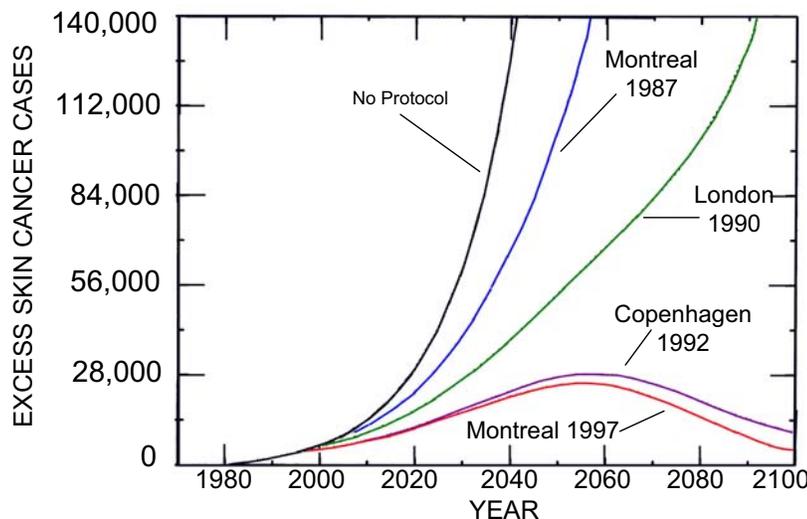

However, there are other processes that result in more ozone:

- Rising CH₄ leads to more stratospheric H₂O, cooling this region of the atmosphere, which slows the rate of all ozone loss cycles.
- Rising CH₄ speeds up the rate of Cl+CH₄, shifting chlorine from ClO into HCl
- Rising CH₄ leads to more HO₂ in the lowermost stratosphere, where there is sufficient CO to result in production of O₃ by so-called "photochemical smog chemistry"

Fig. 6. (a) CH₄-8.5 ozone minus CH₄-2.6 ozone in the 2090s decade, calculated as a percentage of ozone in the CH₄-2.6 simulation. (b) 2090s-decade CH₄-8.5 total column ozone minus CH₄-2.6 total column ozone.

Revell *et al.*, *ACP*, 2012

EXCESS SKIN CANCER CASES IN THE UNITED STATES, PER YEAR, DUE TO OZONE DEPLETION FOR VARIOUS CFC EMISSION SCENARIOS

Longstreth *et al.*, *J. of Photochemistry and Photobiology B*, 46, 20–39, 1998.

See also Slaper *et al.*, Estimates of ozone depletion and skin cancer incidence to examine the Vienna Convention achievements, *Nature*, 384, 256–258, 1996, who state:

The no-restrictions and Montreal Protocol scenarios produce a runaway increase in skin cancer incidence, up to a quadrupling and doubling, respectively, by year 2100.

Second Exam

- Thursday, 11 April, 2:00 pm to 3:15 pm
- CSS 2416
- 6 questions (multi-part)
- Closed book, no notes

- Focus almost entirely on Lectures 9 to 17

- Mix of conceptual questions and simple calculations
- **Please bring a calculator** (we'll have extras if you forget)
- **iPad, iPhone, or any other device able to either go on the web or store notes is not allowed**

- Backbone of course is the lectures; questions may draw upon material from the readings *that has been emphasized in lecture*

- We'll be present: *please let us know if a question requires clarification*
If so, we'll announce clarification to entire class 😊

- **Exam for 633 will differ somewhat from exam for 433**
